```

From this EDA of the categorical variables, we probably should not perform analysis with SECURITY\_DELAY since all of them are classified as 0.

Furthermore, only 9 flights are classified with a weather delay, so it may not be good for our model to include this as a variable for right now.

Overall, the categorical delay predictors I would think we could use are: Carrier Delay, NAS Delay, and Late Aircraft Delay

# Response Variable EDA

# Histogram of ARR\_DELAY

### Predictors vs. Response EDA

### TAXI\_IN / TAXI\_OUT vs. ARR\_DELAY

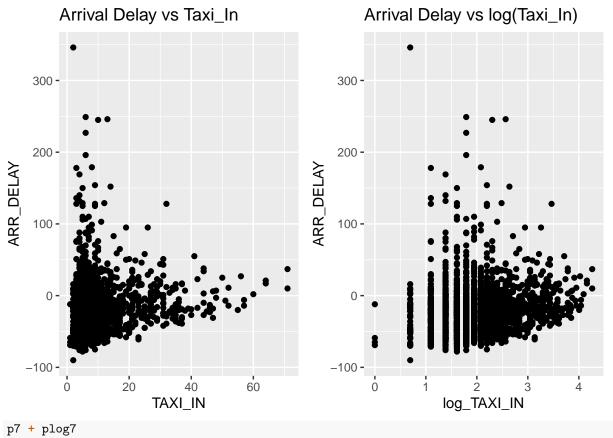

```
p6 <- ggplot(data = flights, aes(y = ARR_DELAY, x = TAXI_IN)) +
    geom_point() +
    labs(title = "Arrival Delay vs Taxi_In")

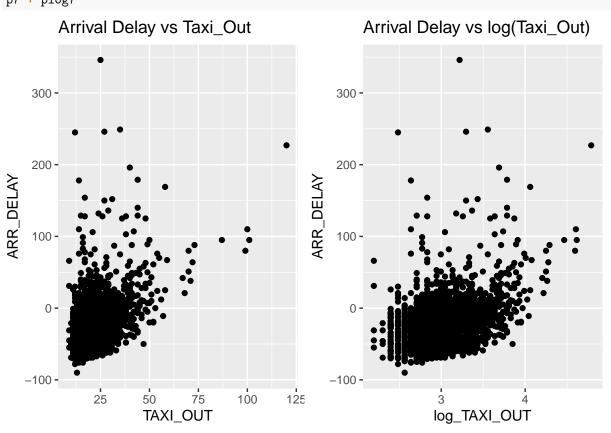

p7 <- ggplot(data = flights, aes(y = ARR_DELAY, x = TAXI_OUT)) +
    geom_point() +
    labs(title = "Arrival Delay vs Taxi_Out")

plog6 <- ggplot(data = flights, aes(y = ARR_DELAY, x = log_TAXI_IN)) +
    geom_point() +
    labs(title = "Arrival Delay vs log(Taxi_In)")

plog7 <- ggplot(data = flights, aes(y = ARR_DELAY, x = log_TAXI_OUT)) +
    geom_point() +
    labs(title = "Arrival Delay vs log(Taxi_Out)")

p6 + plog6</pre>
```

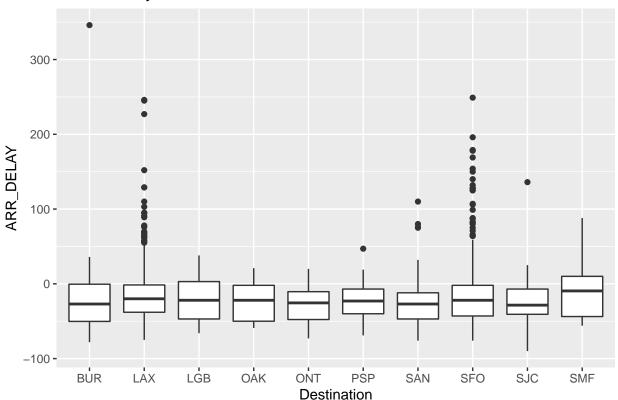

These plots above suggest that we may want to transform the variables at some point.

### DEST vs. ARR\_DELAY

# Arrival Delay vs Destination

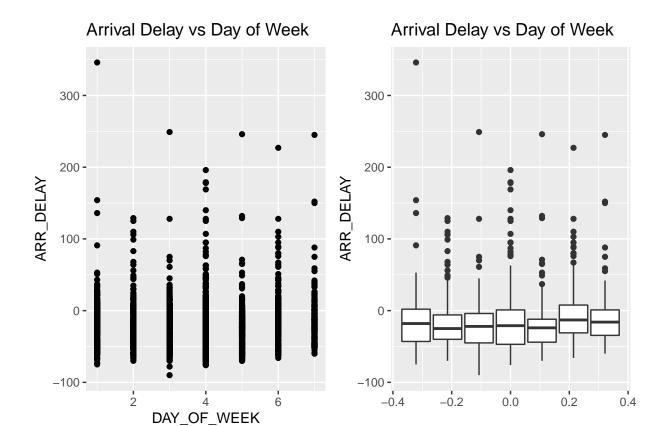

### DAY\_OF\_WEEK vs. ARR\_DELAY

```

    labs(title = "Arrival Delay vs Day of Week")

p9 <- ggplot(data = flights, aes(y = ARR_DELAY, group = DAY_OF_WEEK)) +
    geom_boxplot() +
    labs(title = "Arrival Delay vs Day of Week")

p8 + p9</pre>
```

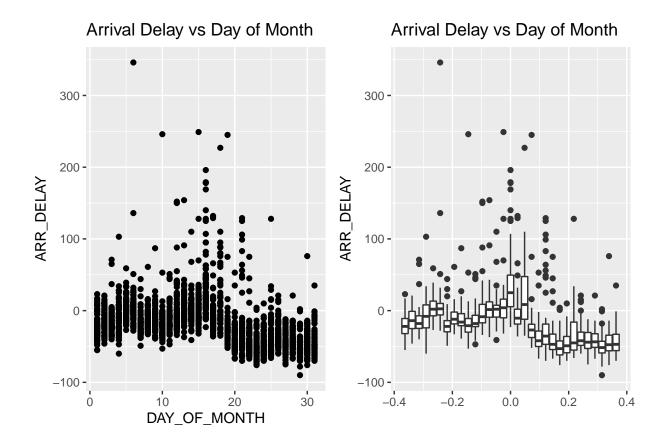

# ARR\_DELAY and DAY\_OF\_MONTH

```

## (3) Tree-Based Models

#### (a) Random Forests

By default, randomForest() uses p/3 variables when building a random forest of regression trees.

```
set.seed(1)
# optimal number of predictors (param = mtry) used = 2 based on CV
rf.delay <- randomForest(ARR_DELAY ~ DAY_OF_MONTH +</pre>
```

```
TAXI_IN +
TAXI_OUT +
DEST +
DEP_DELAY +
CARRIER_DELAY +
NAS_DELAY,
data = train, na.action = na.omit, importance = TRUE,
ntree=10000, mtry=2)
```

Using the importance() function, we can view the importance of each variable.

#### importance(rf.delay)

```

```

Two measures of variable importance are reported. The former is based on the mean decrease in accuracy in predictions on the out of bag samples when a given variable is excluded from the model. The latter is a measure of the total decrease in node impurity that results from splits over that variable, averaged over all trees (this was plotted in Figure 8.9 in the text). In the case of regression trees, the node impurity is measured by the training RSS and for classification trees by the deviance. Plots of these importance measures can be produced using the varImpPlot() function.

```
varImpPlot(rf.delay)
```

# rf.delay

## (b) Boosting

Here we use the gbm() package, and within it the gbm() function, to fit boosted regression trees to the train data set. We run gbm() with the option distribution = "gaussian" since this is a regression problem. The argument n.trees = 150 indicates that we want 150 trees, and the option interaction.depth = 3 limits the depth of each tree.

We see that DEP\_DELAY and DAY\_OF\_MONTH are by far the most important variables. We can also produce partial dependence plots for these two variables. These plots illustrate the marginal effect of the selected variables on the response after integrating out the other variables.
